PersonaSync™

System Request — PersonaSync

CIS 641 Systems Analysis and Design · Week 3 In-Class Activity · September 22, 2026

Project Sponsor: Artie Bowman, PersonaSync owner (solo project, CIS 641, Fall 2026)

Business Need: The AI market is in a race to the top, with LLM providers and tool vendors constantly leapfrogging each other. That works in users' favor as long as they stay adaptable and move to whichever tool fits their needs at the right cost. The catch is that personal context doesn't move with them. People put real time into shaping their AI tools into the assistants, agents, and coworkers they want, and every switch means starting over. There is no uniform way to carry that context between tools, and that is the gap PersonaSync fills. Set it up once, use it everywhere: any tool the user picks up adjusts how it talks and works with them based on who they are.

Business Value:

PersonaSync is still a work in progress. Its goal is to give users ownership of the context that travels with them, so they can move between tools, or start fresh with a new one, without losing the assistants, agents, and coworkers they have already shaped. The data is local-first, stays theirs, and grows with them over time.

That matters because AI runs on the quality of what it is given. A model working from thin, scattered context produces thin results; the same model working from well-kept context the user has authored and confirmed produces work that actually fits the person. PersonaSync is where that context is authored, confirmed, corrected, and reused, so every tool a user picks up starts from good data instead of guesswork. Underneath it sits the Personal Context Layer (PCL), a developer-facing MCP layer that PersonaSync is the first consumer of, not the owner of; other products can read the same layer.

The longer-term goal is for PersonaSync to act as an adapter: it recognizes which model the user is on and translates their context into the form that model responds to best, informed by each vendor's published prompting guidance. That is still a way off. Further out still, the same benefits could apply at the team level, where a shared, well-kept context means everyone's AI tools work from the same understanding of the business.

The market is moving toward this idea. Vendors let users export memory, and Claude now offers a one-time import of ChatGPT and Gemini context, but that is a migration rather than a shared, living persona. A new category of third-party memory layers (MemoryLake, Echo, AI Context Flow, and others) has started filling the gap, mostly by copying chat history across tools over MCP or a browser extension (per vendor product pages, September 2026). PersonaSync sits in that category with a different center of gravity: rather than moving raw memory around, it focuses on the persona, meaning how the AI talks to the user and works with them, plus context the user authors and confirms, with the confidence behind every score. People have used personality frameworks for decades to work better together; PersonaSync lets users bring those results to their AI.

Estimated tangible value (assumptions, not yet measured):

- Session setup cut from roughly 3–5 minutes of re-explaining to under 30 seconds, about 15–25 hours a year per active user
- Existing PCL investment (four-lane data model, seven MCP read tools, scoring engine with confidence, live web app) reused rather than rebuilt
- Opt-in anonymized product analytics open a future path to product insight and research partnerships without touching persona or context content

Business Requirements:

- Store a user's personas and personal context (goals, background, milestones, notes) in one uniform, local-first format any AI tool can read with the user's permission; secure per-user cloud storage and cross-device sync are a follow-on
- Extend beyond the web app to wherever the user works, with two additions that stay out of the way and never need to be open on screen: a browser extension (already on the roadmap) that injects context into any AI and fills everyday forms from saved context, with the user confirming every fill, and a lightweight macOS menu bar app (proposed here for the first time) that runs quietly in the background
- Make it effortless (design goal for the extension and background app): the active persona and context reach the AI tool at the point of use with the fewest possible clicks, so the tool adjusts how it talks and works with the user without any manual re-explaining. Today the path is assemble-and-paste
- Expose context to AI tools through PCL, a read-only MCP interface that is live today, and add a symmetric write path so other tools can feed data in (voice tools like Wispr Flow, health or workout logs, calendars), making PersonaSync™ a plug-in module with inputs and outputs that users connect where it fits and leave out where it doesn't
- Let the user pick which persona or context is active for a session (built, browser-local), share and browse community personas (roadmap), and optionally keep a decision memory that suggests the persona they last used with a tool, which they review before it is saved (proposed)
- Keep the user in charge of what the system believes: goals are always user-authored and go through a confirm-before-save gate, scores are computed and shown with the confidence behind them, and anything the AI inferred rather than the user stated is labeled as such; confirm, correct, and remove across all lanes is in progress
- Give users a clear permissions and sharing log (design commitment, built on the existing omit-record and omit-fields egress gate): what context went to which tool, the ability to review and revoke, and an opt-in for sharing anonymized product analytics, never persona or context content
- Meet a high bar for user experience, visual design, and brand quality; the product should feel like a benefit, never a burden

Special Issues or Constraints:

- One-person team; the class deliverable has to fit a single semester. This scopes the course project, not PersonaSync itself: the class is a vehicle for building on the product, not shrinking it
- Must build on the existing codebase and PCL tooling, deployed as two services; the hosted demo currently runs seeded sample data behind a banner, and abuse protection and billing are a hard gate before any public push
- Third-party AI tool terms of service, Apple and browser extension store review, and how much each tool lets an outside module inject may limit what is possible at the point of use
- Privacy and consent are central: the system holds personal preferences and goals, so secure storage, clear permissions, and revocable sharing must be designed in from the start
- User experience, visual design, and brand quality are a hard requirement, not a polish step; a version that works but is clunky to use does not meet the goal
- Exact feature set is still being scoped; deciding what to build first and why is part of the project
